Walkthrough agenda: choose a usable beginner route

Prepared by **Gage Plott**. November 3, 2026 review proposal. The instructor has acknowledged receiving material and offered to teach after a walkthrough. Detailed review and the final delivery arrangement remain open. Credit material development accurately; teaching delivery is a separate role.

Agreed starting point

Assume zero Python experience. Use live demonstrations that students repeat on their laptops, with complete worked examples and guided discussion. There is no grading, evaluation, assignment, or submitted work. Software assertions check the material; they are not student assessments.

Proposed route to walk through

1. **Day 1, Python/Qiskit:** open and run cells; numbers, text, lists, imports, and function calls; one-qubit X/H circuits, samples, histograms; save/restart.
2. **Day 2, Grover:** two qubits and one target; compare zero, one, and two iterations (target probabilities 1/4, 1, 1/4), then change the target together.
3. **Day 3, QFT/QPE:** see a two-qubit complex phase pattern and inverse-QFT recovery; prepare a target eigenstate and decode three-bit phases 3/8 and 1/8.

Use 75 minutes of activity plus 10 minutes of margin in each 85-minute period. The **two-day fallback** is Day 1 plus Grover. If phase estimation is preferred, it replaces Grover as the single algorithm day. If Shor is essential, agree a brief compiled-N=15 substitution and identify what it replaces; do not append it to an already full session. HHL remains supporting material.

Five decisions to leave with

- Two meetings or three, and exact dates before Thanksgiving. November 16/19/23 were provisional; November 19 is Thursday, conflicting with the listed Monday/Wednesday pattern. No alternative date has been assumed.
- Algorithm priorities and the specific replacement if Shor is required live.
- Laptop operating systems, installation permission, support, and when assisted setup can happen. No independent setup homework is presumed.
- Which quantum ideas are already familiar: amplitudes, phase, measurement, eigenstates, and basic gates. Zero Python does not imply zero quantum knowledge.
- Who delivers after this walkthrough and what further support is needed. Presenter availability/coverage remains unconfirmed until that arrangement is made.

Use the run sheet to rehearse the handoff and the quickstart for laptop operation. Human pacing and learner completion remain untested. No technical code audit is assigned to the instructor.
